Dear Mr. Gratz:

**MAYWOOD SITE - RESULTS OF THE WESTERLY BROOK SAMPLING EVENT**

The purpose of this letter is to transmit the results of the Westerly Brook sampling effort which was conducted in support of the Maywood site remedial investigation. This information will be placed in the administrative record file in July 1993. If you have any comments, please submit them before this time.

Please contact me at (615) 576-5724 if you have any questions.

Sincerely,

A handwritten signature in cursive script that reads "Susan M. Cange".

Susan M. Cange, Site Manager  
Former Sites Restoration Division

Enclosure

## WESTERLY BROOK CHANNEL BANK AND SADDLE RIVER CORE SAMPLING RESULTS

### INTRODUCTION

Soil and sediment samples were collected along Westerly Brook and in the immediate area of its confluence with the Saddle River to determine whether contaminants defined as FUSRAP wastes by the Maywood site federal facilities agreement (Section 1.0 in the Remedial Investigation Report for the Maywood Site, BNI 1992) have been transported to and deposited in these areas. Sample collection and subsequent analyses were performed as described in the "Addendum to the Maywood Site Field Sampling Plan for Westerly Brook/Saddle River" (DOE 1992). This plan delineates the need to perform radiological field screening and sample collection along the banks of Westerly Brook and in the Saddle River floodplain to determine whether deposition of contaminants associated with thorium and lithium processing has occurred. Sampling results are necessary to fully analyze the risks to aquatic receptors in the Westerly Brook and Saddle River areas.

Results of surface water and sediment monitoring conducted in the brook and river since 1984 indicate that radionuclides are not currently being transported from the Maywood Interim Storage Site (MISS) via this pathway. However, low concentrations of lithium, carbon tetrachloride, 1,2-dichloroethene, trichloroethene, and tetrachloroethene have been detected in surface water samples collected downstream of MISS. It has not been established that these organics are originating on MISS.

Samples were analyzed for uranium-238, thorium-232, radium-226, Target Compound List (TCL) compounds, Target Analyte List (TAL) metals, lanthanides, and lithium. To determine contaminant contribution from MISS to surface water and sediment, downstream sampling results are compared with upstream sample results. All sample results were also compared to MISS onsite and representative baseline soil sampling results obtained during remedial investigation work for the Maywood site. The baseline soil samples were collected from three recreational parks in the Maywood area. For informational purposes, comparisons were also made with the New Jersey

Department of Environmental Protection and Energy (NJDEPE) "Cleanup Standards for Contaminated Sites, Proposed New Rules" for residential surface and subsurface soil standards.

## 1.0 SITE DESCRIPTION

Westerly Brook drains an area of approximately 1 km<sup>2</sup> (0.4 mi<sup>2</sup>) in Maywood and Rochelle Park. The brook begins as a natural channel in Maywood and flows southward for approximately 975 m (3,200 ft) in an open channel (upstream of MISS). North of the site, the brook enters a culvert that conducts the flow for 585 m (1,920 ft) beneath MISS. West of the site, the culvert extends approximately 300 m (1,000 ft) before the brook becomes an open channel again, west of St. Ann Place in Rochelle Park. The brook then flows west for approximately 230 m (750 ft) as an open channel before discharging into the Saddle River (Figure 1).

The open channel downstream of MISS is approximately 4 m (12 ft) wide, basically straight, and contains very little sediment. The banks of the channel are approximately 3 m (10 ft) high, steep, and lined with rock walls from the culvert discharge at St. Ann Place to a point 9 m (30 ft) downstream of the Becker Avenue bridge. From this point to the brook's confluence with the Saddle River, the channel has not been altered and exists in its natural state.

The Saddle River is approximately 30 m (100 ft) wide at its confluence with Westerly Brook. The Saddle River drainage area above this point is approximately 130 km<sup>2</sup> (50 mi<sup>2</sup>). The long-term average flow of the Saddle River is 2.83 m<sup>3</sup>/sec (100 cfs).

In the 1960s, the Saddle River channel reach between the New York Susquehanna and Western Railroad and Essex Street was altered by the construction of Interstate 80. Prior to the construction, the Saddle River had a meandering channel, however, the channel was straightened by the construction activities, and most of the old channel was covered with fill.

FIGURE 1

## **2.0 Sampling Locations and Methods**

### **2.1 Westerly Brook**

Soil sampling and radiological surface surveys were conducted at five locations in Westerly Brook (Figures 1 and 2). Cross-sections of the channel banks were surveyed with both a Fidler and a SPA-3 to detect sediment depositional zones exhibiting radioactivity above background. Survey results showed no significant differences over the cross-sections and identified no areas emitting radiation above background.

Because survey results gave no indication of depositional zones contaminated by radionuclides, soil sampling locations were arbitrarily chosen near the bottom of the channel banks at a height approximating the water level during an average storm event. The samples were collected at a depth of 0 to 8 cm (0 to 3 ins).

### **2.2 Saddle River**

Ideally, sampling locations would have been selected to target depositional zones on both sides of the old Saddle River channel downstream of the Westerly Brook confluence. Because the channel was completely altered by construction of Interstate 80, resulting in the placement of fill dirt over the depositional zones on the west side of the river, core samples were collected from only the east side of the river channel below the confluence with Westerly Brook.

Three core samples were collected along a cross-section 5 m (16 feet) downstream of the Westerly Brook confluence with the Saddle River (Figure 2). Core A was taken from the elevated floodplain approximately 3 m (10 ft) from the water's edge. Core B was taken at the water's edge, and core C was taken from within the river approximately 4.6 m (15 ft) from the water's edge. The sampling device was driven to refusal, yielding 1-m (3-ft) cores from locations A and B and a 0.5-m (1.5-ft) core at location C.

The core samples were surveyed with both a Fidler and a SPA-3 to detect contaminated intervals. No activity significantly above background was detected in the samples. However, because the bottom 0.3-m (1-ft) interval of

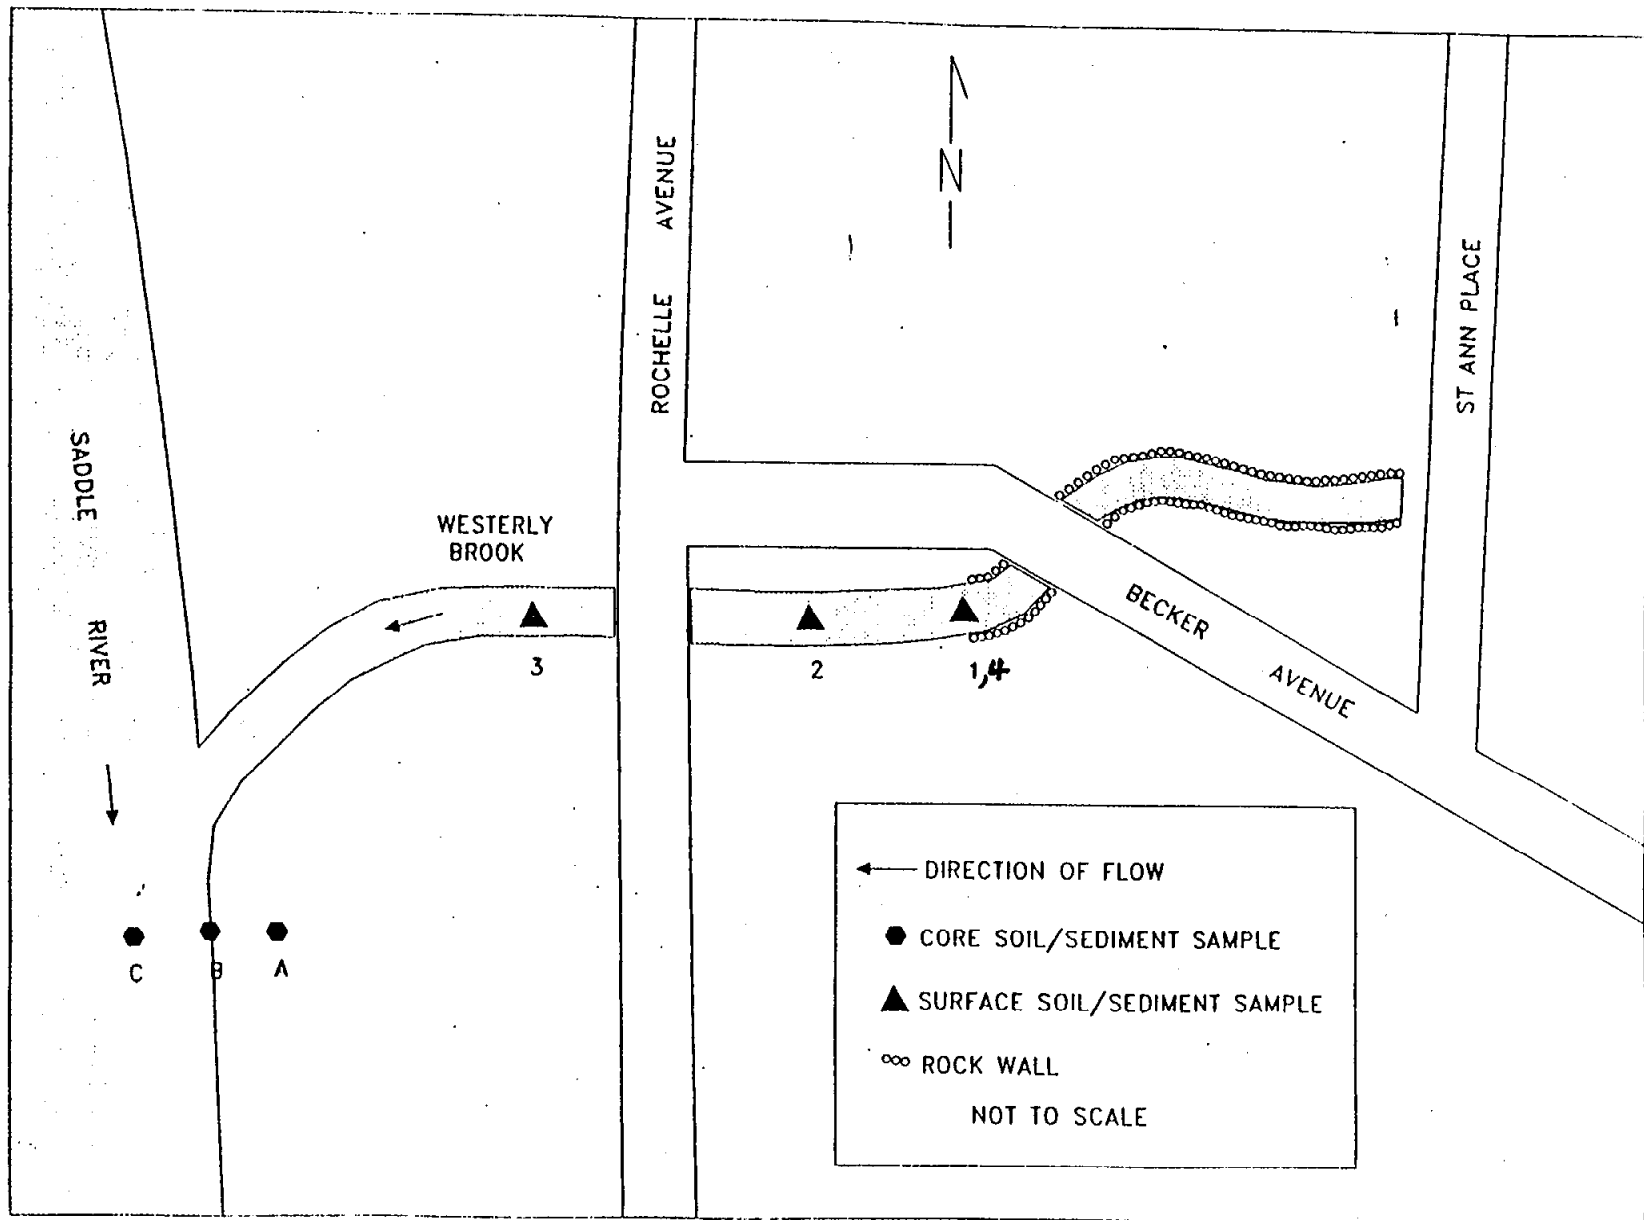

FIGURE 2  
 WESTERLY BROOK/SADDLE RIVER SEDIMENT SAMPLE LOCATIONS

each core exhibited slightly higher survey readings (approximately 10 cpm when surveyed with the SPA-3), the lower portion of the core was selected as the sample to be analyzed for the various radiological and chemical parameters.

### **3.0 Evaluation of Radiological Contaminants**

As can be seen in Table 1, results of the radiological analyses performed on the Westerly Brook and Saddle River core samples are at or near the analytical detection limits in most cases. Results for radium-226 and thorium-232 were all well below FUSRAP guidelines of 5p Ci/g for surface soil [less than 15 cm (6 in) deep] and 15 pCi/g for subsurface soil [15 cm (6 in) deep or greater].

The absence of radiological contamination indicates that sediment originating at the Maywood site has not been deposited along the banks of Westerly Brook or in the Saddle River. Radiological contaminants tend to be tightly bound to sediment particles and, therefore would have been transported with sediment migrating from the site and would be evident downstream.

### **4.0 Evaluation of Chemical Contaminants**

Samples for chemical analyses were collected from the same locations as those for radiological analyses. The samples were analyzed for volatile organic compounds (VOCs), base/neutral and acid extractable compounds (BNAEs), pesticides, polychlorinated biphenyls (PCBs), target analyte list (TAL) metals, and lanthanides.

**Volatile Organic Compounds.** Analyses for VOCs detected the presence of acetone in sample B (23  $\mu\text{g}/\text{kg}$ ) and C (38  $\mu\text{g}/\text{kg}$ ) from the Saddle River (see Figure 2). These concentrations are low and well below the NJDEPE proposed standard of 50 mg/kg. No other VOCs were detected. The absence of acetone in Westerly Brook soil samples, routine environmental monitoring surface water samples, or MISS onsite soil samples further indicates a source other than MISS.

**Base/Neutral Acid and Extractable Compounds.** Table 2 presents the analytical results for base/neutral and acid extractable compounds (BNAEs).

<sup>e</sup>Sample 4 is a field duplicate for 1.

Analytical results indicate that although the 15 BNAEs detected in the brook and river samples were also detected in MISS soil samples, the site's contribution to downstream BNAE concentrations is probably small or negligible, and the presence of the compounds is primarily a result of the industrialized nature of the area, the high population density, and litter observed in Westerly Brook and the Saddle River. The following observations support this hypothesis:

- o The BNAEs found in MISS onsite soil samples were detected infrequently; none were detected above mean background soil concentrations in more than 15 percent of the samples analyzed.
- o BNAEs have not been detected in environmental monitoring surface water samples taken downstream of MISS.
- o Eleven of the 15 compounds detected in the study samples were detected in upstream as well as downstream samples. Two of the remaining four compounds were detected only in an upstream sample, and two were detected only in a sample from the Saddle River.
- o NJDEPE has proposed soil standards for 13 of the 15 BNAEs detected. Benzo(A)anthracene, benzo(A)pyrene, benzo(G,H,I)perylene, benzo(k)fluoranthene, chrysene, and indeno(1,2,3-cd)pyrene were detected at concentrations above the proposed standards in upstream samples. These same BNAEs, except benzo(G,H,I)perylene, were also detected at concentrations above the proposed standards in downstream samples.
- o Visual inspections of Westerly Brook and the Saddle River revealed an abundance of litter ranging from recently deposited paper, plastics, and fabrics to automotive oil filters, scrapped parts, and building materials. Much of the debris is partially or mostly

buried in sediments, indicating that littering in the brook and river has been taking place for a long time.

It should be noted that when a given BNAE was detected at all three sampling locations, the maximum concentrations detected in downstream samples from Westerly Brook were approximately twice those detected in upstream samples. Furthermore, concentrations in samples from the Saddle River were generally 2 to 3 times higher than concentrations in downstream samples from Westerly Brook. Possible explanations for the increasing concentrations downstream include:

- o The variable nature of sampling results when a heterogeneous medium is sampled at a few sampling locations.
- o Proximity to local sources of contamination present within or draining into the brook and river.

BNAE contamination of the soil and sediment is probably common throughout the area resulting from the long-time high population density and the industrial businesses in the area. If Westerly Brook were the only contributor of BNAEs to the river, concentrations of BNAEs would be expected to be significantly lower in the river than in the brook because of dilution in the larger volume of water. The concentrations increase, however, which suggests sources other than Westerly Brook.

**Pesticides and PCBs.** Analytical results for pesticides and PCBs are presented in Table 3. The results indicate that pesticides are not migrating from MISS. The only pesticide detected was 4,4'-DDD in samples B (0.067 mg/kg) and C (0.220 mg/kg) from the Saddle River. These concentrations are well below the NJDEPE proposed standard of 100 mg/kg for subsurface soil. The absence of pesticides in Westerly Brook samples indicates that the source is upstream in the Saddle River watershed.

The PCB arochlor-1254 was detected in all upstream and downstream samples from Westerly Brook and in sample A from the Saddle River (see Figure 2). Results for all of the Westerly Brook samples were above the NJDEPE

<sup>e</sup>Sample 4 is a field duplicate for 1.

proposed soil standard of 0.45 mg/kg; however, because PCBs have not been detected in soil samples from MISS and the maximum upstream and downstream sampling results for Westerly Brook (13 and 18 mg/kg, respectively) are similar, it can be concluded that MISS is not contributing PCBs to downstream soils or sediments.

**Metals.** Most of the 26 metals analyzed for are natural components of the earth's crust and commonly detected in soils and sediments. In an effort to focus on metals that may have migrated from MISS, only metals known to be constituents of thorium and lithium process wastes are discussed. Analytical results for these metals (arsenic, cobalt, copper, lead, lithium, nickel, selenium, and vanadium) are presented in Table 4. Table A-3 presents a complete list of analytical results for metals.

Analytical results for metals indicate that activities at MISS have had no discernable effect on metal concentrations in soil and sediment in Westerly Brook and the Saddle River. In all samples, concentrations of cobalt, nickel, selenium, vanadium, arsenic, and lithium are comparable to background concentrations and are below proposed NJDEPE standards. Analytical results of surface water and sediment samples collected from Westerly Brook in support of MISS environmental monitoring and remedial investigation work indicate the presence of low concentrations of lithium (less than 1 mg/L) in the surface water downstream of the site. Analysis of filtered surface water samples demonstrated that the lithium is primarily in solution. This finding correlates well with the absence of lithium in past environmental monitoring sediment samples the bank and core samples collected for this study. Apparently low concentrations of lithium leaving the site are being carried via surface water to the Saddle River where the lithium becomes very dilute and remains in solution.

Concentrations of copper are above background concentrations but are highest in an upstream sample, indicating a source other than MISS. Most samples (upstream and downstream) also contain lead at concentrations above background. All of the downstream samples and one upstream sample contain concentrations of lead greater than the NJDEPE proposed standards. The

<sup>a</sup>Sampling locations are shown in Figures 1 and 2. Locations 5, 6, and 7 are on Westerly Brook, upstream of MISS.

<sup>b</sup>Analytical result for soil samples from local parks (BNI 1992).

<sup>c</sup>From the New Jersey Department of Environmental Protection and Energy's "Cleanup Standards for Contaminated Sites, Proposed New Rules."

<sup>d</sup>Sample 6 is a field duplicate for 5.

<sup>e</sup>Sample 4 is a field duplicate for 1.

following observations indicate that there are likely many contributing sources (other than activities at MISS) that are primarily responsible for the lead present in the brook and river soils and sediments:

- o Lead was detected consistently above background in upstream as well as downstream samples.
- o Visual inspection of the brook and river revealed large quantities of discarded metal, including pipes and oil filters (some possibly containing lead).
- o The brook and river drain an area that has been densely populated with industries, people, and automobiles (burning leaded gasoline) for decades.

**Lanthanides.** Analyses for lanthanides were performed because lanthanides are known to be common constituents of the monazite sands processed by the former Maywood Chemical Works. Lanthanides detected are presented in Table 5. Concentrations of lanthanides detected in background soil samples collected for the Maywood site remedial investigation have also been included for comparison. Analytical results indicate that lanthanides have not migrated from MISS to the soils and sediments in Westerly Brook and the Saddle River. Concentrations of the 8 lanthanides detected are all low and approximately equal to or less than the maximum concentrations measured in the background soil samples.

#### **Conclusion**

The data resulting from this sampling event suggest that radionuclides and chemicals currently or historically present on MISS have not discernably accumulated in soils and sediments in Westerly Brook or the Saddle River. Supporting this conclusion is the fact that analytes of interest were either not detected at all in the study and/or onsite samples, they were detected in the study samples at concentrations comparable to background concentrations, or they were detected above background concentrations in both upstream and downstream samples.
