Formerly Utilized Sites Remedial Action Program (FUSRAP)

ADMINISTRATIVE RECORD

for Maywood, New Jersey

U.S. Department of Energy

United States Government

Department of Energy

memorandum

DATE: AUG 31 1995

SEP 6 9 33 AM '95

REPLY TO EM-421 (W. A. Williams, 301-903-8149)
ATTN OF:

SUBJECT: Elimination of Maywood Vicinity Property

TO: L. Price, OR

The attached radiological survey report, entitled Radiological Survey Results at 1 Shady Lane, Lodi, New Jersey (LJ095), identifies background levels of radioactive substances at that property. Accordingly, the property is not designated for remedial action under the Formerly Utilized Sites Remedial Action Program.

ACKNOWLEDGMENTS

Research for this project was sponsored by the Office of Environmental Restoration, U. S. Department of Energy, under contract DE-AC05-84OR21400 with Martin Marietta Energy Systems, Inc. The authors wish to acknowledge the contributions of D. A. Roberts, D. A. Rose, and J. M. Lovegrove of the Measurement Applications and Development Group for participation in the sample preparation and analyses, editing, graphics, and reporting of data for this survey. The surveying assistance of the staff on the survey team is also gratefully acknowledged.

ABSTRACT

The U. S. Department of Energy (DOE) conducted remedial action at the Stepan property in Maywood, New Jersey and several vicinity properties in Lodi, New Jersey as part of the Formerly Utilized Sites Remedial Action Program (FUSRAP). These properties are in the vicinity of the DOE-owned Maywood Interim Storage Site (MISS), adjacent to the former Maywood Chemical Works facility. The property at One Shady Lane, Lodi, New Jersey was not one of these vicinity properties but was surveyed by DOE at the request of the owner.

At the request of DOE, a team from Oak Ridge National Laboratory conducted a radiological survey at this property. The purpose of the survey, conducted in November 1994, was to confirm whether remedial actions were to be performed on the property in order to be in compliance with the identified guidelines. The radiological survey included surface gamma scans and gamma readings at 1 meter, and the collection of soil samples for radionuclide analysis.

Results of the survey demonstrated that all radiological measurements on the property at One Shady Lane, Lodi, New Jersey, were comparable to background levels in the area, and well within the limits prescribed by DOE radiological guidelines. Based on the results of the radiological survey data, this property does not meet guidelines for inclusion under FUSRAP.

RADIOLOGICAL SURVEY RESULTS AT 1 SHADY LANE, LODI, NEW JERSEY (LJ095)*

INTRODUCTION

Thorium ores were processed by the Maywood Chemical Works (MCW)¹, Maywood, New Jersey, between 1916 and 1959. The MCW ceased thorium processing in 1959 and the 30-acre property was sold that same year to Stepan Chemical Company. During the early years of operation, MCW stored wastes and residues in low-lying areas west of the processing facilities, now called the Maywood Interim Storage Site (MISS). Subsequently, residuals containing radioactive materials migrated off-site to the surrounding area, and the Stepan property and several vicinity properties were designated by Congress for remedial action as a result of the 1984 Energy and Water Development Appropriations Act, along with other sites.

The waste produced by the thorium extraction process was a sand-like material containing residual amounts of thorium and its decay products, with smaller quantities of uranium and its decay products. Because some of the wastes had been carried downstream by Lodi Brook, and some area residents had also used the sand-like wastes as mulch in their yards, the properties in the vicinity of the MCW were included as a decontamination research and development project under the DOE Formerly Utilized Sites Remedial Action Program (FUSRAP). Figure 1 shows the location of Lodi, New Jersey, relative to the former MCW, now the DOE-owned Maywood Interim Storage Site.

At the request of the DOE, a group from Oak Ridge National Laboratory (ORNL) conducted investigative radiological surveys of several properties surrounding the former processing plant. The property at One Shady Lane, Lodi, New Jersey, was not included in the earlier investigations; however, since the property was adjacent to a park which had been surveyed and found to contain some areas above guidelines, the owner requested that his property be surveyed also.

In November 1994, ORNL conducted an ad hoc radiological survey at the request of DOE. A complete gamma scan was performed and four soil samples were collected and analyzed for radionuclide concentrations.

A drawing of the property at One Shady Lane is shown in Fig. 2. Photographs taken in November 1994 of the property are shown in Figs. 3-5.

*The survey was performed by members of the Measurement Applications and Development Group of the Health Sciences Research Division of Oak Ridge National Laboratory (ORNL) under DOE contract DE-AC05-84OR21400.

SURVEY METHODS

A comprehensive description of the survey methods and instrumentation used in this survey is given in *Procedures Manual for the ORNL Radiological Survey Activities (RASA) Program*, ORNL/TM-8600 (April 1987)², and *Measurement Applications and Development Group Guidelines*, ORNL-6782 (January 1995)³.

SURFACE RADIATION MEASUREMENTS

Gamma radiation levels were determined using a portable sodium iodide (NaI) gamma scintillation probe connected to a Victoreen ratemeter. Measurements were recorded and converted to microrentgens per hour ($\mu\text{R/h}$). Because NaI gamma scintillators are energy dependent, measurements of gamma radiation levels in counts per minute (cpm) are normalized to pressurized ionization chamber (PIC) measurements to estimate gamma exposure rates in $\mu\text{R/h}$.

SOIL SAMPLING AND ANALYSIS

Surface and subsurface soil samples were systematically collected over the back and front yards of the property. Two samples were taken from the front yard and two from the backyard (locations of the samples are shown in Fig. 2). All samples were analyzed for thorium, radium and uranium. At each sampling location, the gamma radiation levels are measured at each six-inch increment in the sample hole. The gamma radiation levels give an indication of possible nearby radioactive materials and their location.

SURVEY RESULTS

Current DOE guidelines for sites included within the FUSRAP are included in Table 1.4.⁵ Typical background radiation levels for the northern New Jersey area are given in Table 2.6.⁷ These data are provided for comparison with survey results presented in this section. All direct measurement results presented in this report are gross readings; background radiation levels have not been subtracted. Similarly, background concentrations have not been subtracted from radionuclide concentrations in soil samples.

SURFACE RADIATION MEASUREMENTS

A gamma scan was conducted over the grassy areas of the front and back yards, sidewalks, and driveway. Gamma exposure measurements generally ranged from 7-13 $\mu\text{R/h}$ at the surface in the front, side and back yards. A maximum range of 10 to 16 $\mu\text{R/h}$ was measured between the sidewalk and the front of the brick house, where natural constituents in the building materials can influence gamma measurements (see Fig. 2). All the measurements are comparable to the typical background radiation levels found in the northern New Jersey area (Table 2).

SOIL SAMPLING AND ANALYSIS

Systematic soil samples were collected from the front and back yards. All samples were analyzed for uranium, radium and thorium concentrations. Results of the soil analysis showed that radionuclide concentrations in both surface and subsurface samples ranged from 0.71 to 1.1 pCi/g, 0.81 to 1.1 pCi/g, and 0.70 to 2.4 pCi/g for ^{226}Ra , ^{232}Th , and ^{238}U , respectively. Concentrations of radium and thorium are comparable to background levels for the northern New Jersey area (Table 2), and well below DOE guidelines in surface and subsurface soil of 5 and 15 pCi/g, respectively. Concentrations of ^{238}U are also well below the site specific limits prescribed for uranium (Table 1). Sample locations are shown on Fig. 2 and results of radionuclide analysis are listed in Table 3.

SIGNIFICANCE OF FINDINGS

Gamma exposure levels on the property ranged from 7 to 16 $\mu\text{R}/\text{h}$. For comparison, background levels for the northern New Jersey area average $\sim 9 \mu\text{R}/\text{h}$. Concentrations of uranium, thorium, and radium found in the soil samples taken from the front and back yards were comparable to background levels in the area and are well below DOE guidelines for these radionuclides.

The measurements taken during this radiological survey at One Shady Lane, Lodi, New Jersey indicate results that are well within the limits prescribed by DOE radiological guidelines. Therefore, based on these findings, this property does not meet guidelines for inclusion under FUSRAP.
